I-O/WIPA Notes

NA-30-06

Here, we cannot simply write

$$GVA^* = GVA + m_T + m_F,$$

because the interest transferred by P+T to households \neq to int. transferred to Finance by HH

So question arises: is the excess of int. paid by HH to F greater int. received by HH from P+T, simply a disguised form of surplus value transferred?

- If so, then $GVA^* = GVA + m_T + m_F$

- If not, then $\Pi > S - \text{Cost of Capital}$
(i.e. $GVA^* < GVA + m_T + m_F = S - (w+m)_{T+F}$)

Revised NIPA/SV Estimation: Talk

3/29/89

- ① When I first did this, we built-up Y^* because we had ^{worked out} only revenue side (Marr now, we can show double-account transformation, so derive it by subtraction from Y)
- ② ~~Existing~~ Invd + Trade Sectors: $Y^* = (W_p + T_p) + (W_T + T_T) + (m_t + d_t)$

$$Y^* = Y_p + Y_T + (m_t + d_t)$$

- (i) note that like I-O, NIPA, we do not count gross output of prod. sector twice; once as output of prod sector & once as ^{price} cost of goods resold. Like them, we count only the ^{trade sector} sales portion above the price of goods to be resold - otherwise double counting
- (ii) But unlike NIPA/I-O, we count only all of the GTM, not just UA, since all of this represent surplus value absorbed in trading activities

2. Existing NIPA accounts: $Y = Y_p + Y_T + Y_{FIRE} + Y_G + Y_{HI}$

- (i) Y_p ✓ (ii) $Y_T \rightarrow Y_T + m_t + d_t$
- (iii) Y_G - double counts w_p (see notes)
- (iv) Y_{FIRE} - decompose into elements & treat these separately according to whether
- They are like a trading activity (BR)
 - They are like transfers of s.v. or transfer of revenue
 - They are fictitious

3. ~~SV~~ Y_{HI} $\left\{ \begin{array}{l} \text{wages of non-profit institution workers} \\ \text{(transfer of revenue)} \\ \text{wages of domestic workers (Non-commodity services)} \\ \text{Commodity services} \\ \text{Cap: Commodity} \end{array} \right.$

Revised MPA/SoV. Estimates: Talk

3/29/89

4. Final results: estimate γ^* simply by

$$\gamma^* =$$

V, S, VTS

Correct Procedure vs. Procedure in NIPA/SU paper

2/9/84

I Correct Measure

1. $Y^* = Y_p + TR_{BR}^* + [TR_{BR}^k + TR_{GRFB}]_{P+T}$? shouldn't this be of prod. & trade sectors only?

* (if P+T sector pays interest F_B and then $F_B = TR_{FB}$ is then partially passed on as GR or F paid by this sector, it is counted twice. If used for TR_{FB} where $TR_{FB}^k = GFM$ of trade sector $= Y_{FT} + m_{FT} + d_{FT}$

~~TR_{GRFB}_B~~ = ~~Total Revenue of Sector receiving interest and \rightarrow extent from business~~ (excludes costs of goods sold)

2. ~~TR_{BR}^*~~ $(TR_{BR}^*) = TR_{BR} - A_{BR} = (TR_{BR})_{P+T} + (TR_{BR})_{GR} - A_{BR}$

$(P+T)?$ = Adjusted total revenue of business & consumer building rentals paid by productive and Trade sectors

$(TR_{GRFB})_B =$ Total Rent of Business GR and Finance sectors

$(P+T)?$ = Total Ground Rent and Finance Charges paid by Business

$= (GR)_B + F_B$

II ^{Previous} Our Measure $Y^{*'} = Y_p + TR_T^* + [R_B + F_B]_{P+T}$

(in Marxian Categories & NAT & Rents down Dec 1978)

$R_B =$ Net business rent paid $= (TR)_{BRB} + (GR)_B$

$F_B =$ Net " " " "

2/9/84

III Comparing $Y^v = \text{correct measure}$
 $Y^{*'} = \text{our ~~current~~ ^{previous} measure}$

$$(i) Y^* = Y_p + TR_T^* + [(TR_{BRB}^v - A_{BRB}) + (TR_{BRc}^v - A_{BRc})] + GR_B^v + F_B^v$$

$$(ii) \text{Alternatively, } Y^{*'} = Y_p + TR_T^{*'} + [(TR_{BRB}^v + GR_B^v) + F_B^v] [TR_{BRc}^v - A_{BRc}]$$

$$\therefore Y^* = Y^{*'} + [(TR_{BRc}^v - A_{BRc}) - (A_{BRB})]$$

$$\therefore Y^{*'} = Y^* + (A_{BRc} - TR_{BRc}^v) + A_{BRB}$$

IV Note that we cannot estimate Y^* directly without estimating TR_{BR}^* and specially TR_{GRFB} — and this would in any case require estimating R_B and F_B and hence in effect calculating $Y^{*'}$ first and then adjusting.

Calculation of Variable Capital ① 8/2/84
 (See 10/19/84) "New Procedure"

1. To begin with, we look at Employee Compensation (EC) which is

$$EC = (\text{Wages} + \text{All Salaries} + \text{Employer Contrib. to Social Security})$$

(1) This EC measures labor cost (gross labor income) of all employees. As such

(a) it includes corporate officers, ^{at least a} ~~which~~ portion of which should be excluded (altogether) on grounds that their labor is all at level of capitalist)

(b) it excludes ^{all} in come of self-employed persons (PROPRIETORS / PARTNERS). Here, at least a portion should be included, insofar as it corresponds to the wage ~~equivalent~~ ^{variable capital} of their productive activities (the productive portion of the total personal labor of self-employed persons who own profit-making enterprises)

(ii) Conceptually, corporate officers are managers of corporations, and proprietors/partners ^{of capitalist enterprises} are capitalist ^{capitalist} owners/managers of unincorporated enterprises. So at this abstract level, we have to treat them as conceptually equivalent since the difference between corporate capital & unincorporated capital is second order

2. First, let us get the proper conceptual total

$$EC^+ = EC + WEQ = (\text{Wages} + \text{Employer Contrib.}) + \text{COST WEQ}$$

Gross Wages = W' + other labor income

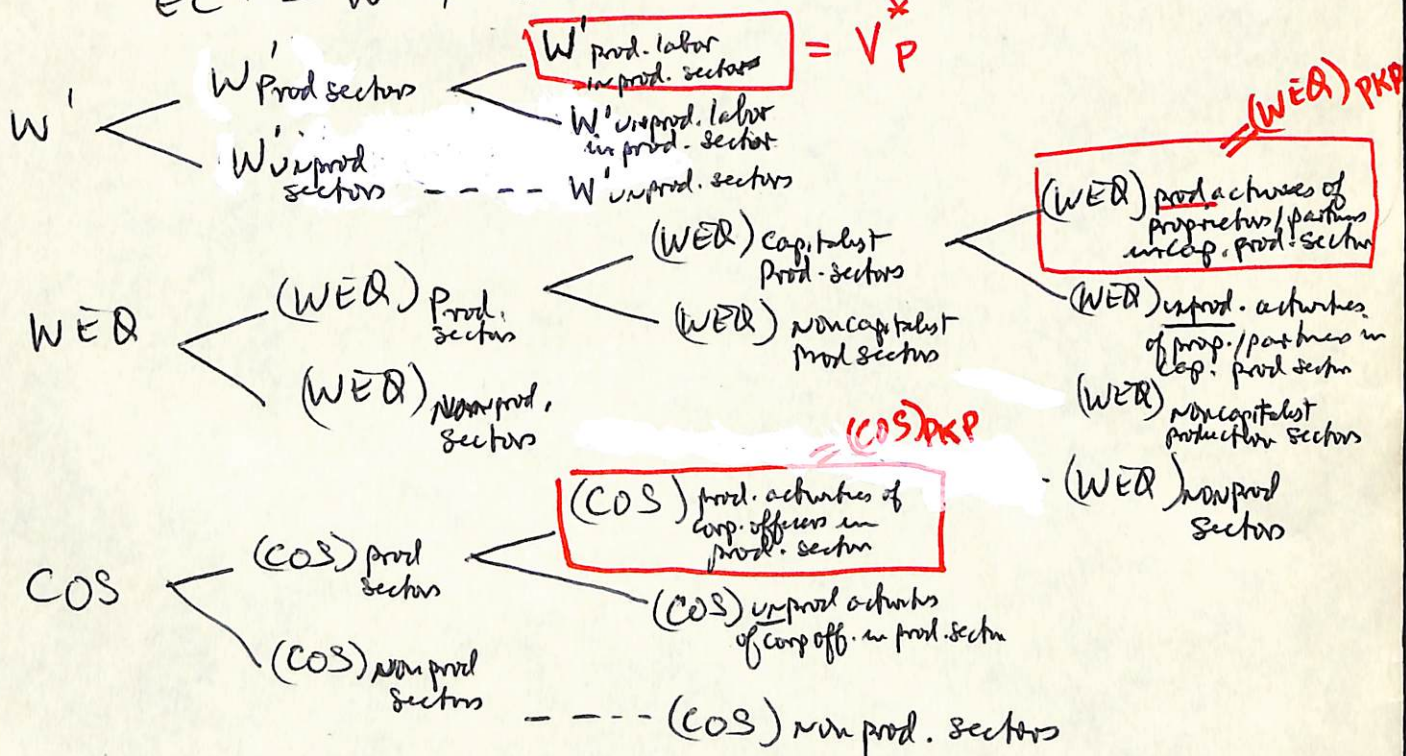

$$EC^+ = W' + WEQ + COS$$

Calculation of Variable Capital

(2)
8/2/84

To proceed from EC^+ , we need to deal with the productive/unproductive split of breakdown of each of the three components of EC^+

$$EC^+ = W' + WER + COS$$

3. Conceptually, there are two different measures of variable capital & they have to do with whether or not the wage-equivalent of ^{the productive activities} both corporate and noncorporate capitalist enterprises is counted as variable capital.

(1) From one point of view, there can be productive component to the labor of capitalist managers, e. F. (Capital I, Penguin, p. 1048)

~~From this~~

Calculation of Variable Capital

3

8/2/84

(ii) From another point of view, there is a question whether this labor is ^{actually} first exchanged against variable capital, or whether it is merely an ~~formal~~ apparent similarity

(iii) If it is treated as variable capital, we ~~need to~~ ^{have}

a) ~~(WED)~~ $(WED)_{PKP} + (COS)_{PKP} = V_{PKP}^*$ = variable capital of prod. activities of capitalist managers of production enterprises

$$\text{and } V^* \equiv V_p^* + V_{PKP}^*$$

b) If not, $V^* = V_p^*$

4. Empirically, none of this may matter because

(i) $(COS)_{PKP}$ may be taken to be effectively ^(prod.) very small relative to W_p in ^{corp} sector

(ii) $(WED)_{PKP}$ may be larger as a portion of WED , but given capitalist/non-capi. division, & then prod./unprod within capitalist ~~non-corp~~ sector, this too is small

→ E-G. ...

(iv) So, empirically we can assume $V_{PKP}^* \equiv V_p^* = (W_p^*)_p$

7/30/85

1972 of Earlier Tables: Differences

I. Secondary Products

1. 1972 redefines all secondary products

(1) Output of secondary product is reallocated to industry which ~~is a~~ primarily produces such products

(ii) ~~Input~~ A relevant mixture of inputs is also reallocated

(1972 Def. & Convention, p. 49)

2. Earlier tables used mixture of redefinition and transfers.

~~(iii)~~ Transfers:

(i) Secondary product was treated as if it was sold to primary producer, and then added to the output of that (primary) industry.

1972 of Earlier Tables: Differences 7/30/88

(11) To trace this, let us first imagine that there are two ~~industries~~ ^{products} (Steel & iron) which ^{then} ~~appear~~ as two establishments

$A = \text{Steel} + \frac{1}{2} \text{iron}$

$B = \frac{1}{2} \text{iron}$

By Commodity

	Steel	Iron	C	I	Go
Steel	50	100	350	500	1000 ✓
Iron	100	300	300	300	1000 ✓
W	250	300			
T	600	300			
Go	1000	1000-			

To combine these by establishments table must be reallocated and rebalanced

- a) $\frac{1}{2}$ of iron column must be combined with steel to get Establishment A input structure
- b) Then, $\frac{1}{2}$ of steel sales must be added Est. A row to get Establishment A sales

7/30/80

By Establishment A = Steel + 1/2 Iron
 B = 1/2 Iron

	A	B	C	I	GO	TR
A	225	125	500	650	1500	
B	125	75	150	150	500	
W	400	150				
T	750	150				
GO	1500	500				
TR						

(14) Pre-1972 I-O tables would reallocate by method of transfer

a) Iron in Establishment A is treated as if sold to Establishment B

It therefore is still counted as Establishment A output

Aggregation

$$A+B = (100 + 550 - 50) + 250 + 150$$

$$= 550 = 225 + 125 + 125 + 75 + 650 + 800$$

$$A_A + A_B + B_A + B_B - TR_B$$

Iron purchased by B is therefore ~~50~~ added to B's ⁸⁰⁰ output (p. 49)

W 550

T 900

$$2000$$

$$= 60 - TR$$

4
7/30/85

Iron in EST A = \$500 by construction

- Add \$500 to A's sales to B
- Add \$500 to B's output \Rightarrow allocate it along B's row
- Rebalance table, since now it looks like this:

	A	B	C	I	Go
A	225	<u>625</u> (125+500)	500	650	<u>2000</u> (1500+500)
B	125	75	150	150	500
w	400	150			
π	750	150			
Go	1500	<u>1000</u> (500+500)			

uses allocations proportions of B here

Re Balance by moving \$500 worth of iron distribution (your row) from A to B. Then list amounts transferred in transfer row & column (for use in aggregation)

	A	B	C	I	Go	π R
A	100 (225-125)	550 (625-75)	350	500	<u>1500</u> (2000-500)	<u>500</u>
B	250 (125+125)	150 (75+75)	300	300	<u>1000</u> (500+500)	-
w	400	150				
π	750	150				
Go	1500	1000				
π R	1500	1500				

2. (iv) End Result is a table which has inflated intermediate inputs + GO relative to (True) Commodity Table
 - Note that GVA, GFD are not altered.

(TRUE) Commodity Table

	<u>Steel</u>	<u>Iron</u>	<u>C</u>	<u>I</u>	<u>GO</u>
Steel	50	100	350	500	<u>1000</u>
Iron	100	300	300	300	<u>1000</u>
W	250	300			
T	600	300			
GO	<u>1000</u>	<u>1000</u>			

Pre-1972 I-O Table

	<u>Steel</u>	<u>Iron</u>	<u>C</u>	<u>I</u>	<u>GO</u>	<u>TR</u>
Steel	100 ^x	550	350	500	<u>1500</u>	500 = TR ₁
Iron	250 ^x	150	300	300	<u>1000</u>	-
W	400	150				
T	750	150				
GO	<u>1500</u>	<u>1000</u>				
TR	-	500 = TR ₂				

	<u>Steel</u>	<u>Iron</u>	<u>Total</u>
Devaluation of GO	+500	-	+500
" " GVA	+300	-300	-
" " GFD	-	-	-

→ Total inputs are inflated
 } But total VA, FD is not changed

7/30/85

Aggregation of these sectors cancels out this distortion, since ~~of~~ transfer column & rows are used to adjust aggregates

EG, if we aggregate Pre-1972 IO Table,

	<u>Prod</u>	<u>C</u>	<u>I</u>	<u>GO</u>
Prod	550 <small>= 100 + 550 - TR₁ + 250 + 150</small>	650	800	2000 ✓
Wp	550	—	—	
TP	900	—	—	
GO	2000 ✓			

7/30/85

3. Now consider an example of P + T

(i) True Table

	<u>Prod</u>	<u>Trade</u>	<u>C</u>	<u>I</u>	<u>Go</u>
<u>Prod</u>	50	100	350	500	1000
<u>Trade</u>	100	300	300	300	1000
<u>W</u>	250	300	↓ GFD* = 1850		
<u>π</u>	600	300			
<u>Go</u>	1000	1000	↓ GVA* = 1850		

(ii) Establishment Table : $A = \text{Prod} + \frac{1}{2} \text{Trade}$
 $B = \frac{1}{2} \text{Trade}$

	<u>A</u>	<u>B</u>	<u>C</u>	<u>I</u>	<u>Go</u>
<u>A</u>	225	125	500	650	1500
<u>B</u>	125	75	150	150	500
<u>W</u>	400	150	↓ 1650 < GFD* = 1850		
<u>π</u>	250	150			
<u>Go</u>	1500	500	↓ 1650 < GVA* = 1850		

Note that ^{total}GVA & GFD are same as in true table
 But now ^{total}GVA* ≠ values in solid boundaries
 because mp now includes portion of m_T.

8
7/30/85

(iii) Now Pre-1972 style I=O with transfer (same as in 2 (iii))

	Prod	Trade	C	I	GO	TR
Prod	100	550	350	500	1500	500 (TR ₁)
Trade	250	150	300	300	1000	
W	400	150	2150 > GFD ^o = 1850			
T	750	150	2150 > GVA ^o = 1850			
GO	1500	1000	GVA ^o = GVA ^o + 1/2 * T = 1850 + 1/2 * (600) = 2150			
TR	-	500 (TR ₂)	and x = TR _{2} / GFD = 500 / 2150, so x / (1-x) = 1 ⇒ Adj = GVA^o = 300}			

Now, once again $GVA = GFD = 1450$

but shaded outlined areas do not add up to GVA^o , GFD^*

Moreover, the difference is not simply due to "Transfer" col/row, since these adjustments themselves only were adjustments to the recorded data in Establishment form and this form itself is the thing which needs to be adjusted. [3 (iii)]

7/30/85

Upside of this is that the only proper way to deal with pre-1972 tables is to recalculate them in 1972-form — which means that

4. Summary

(I) ~~As~~ for as production sectors are concerned, proper aggregation

(i.e. taking out transfers, as in p. 6) will cancel out transfers and also eliminate errors in establishment form vs-a-vs (true) commodity form

(II) As far as production sectors versus trade sectors, the problem is one of going back & redefining, rather than transferring, the trade "service" within production ~~sect~~ establishments

Note that in any case, $GVA = GPD = Y$ is not affected

BUT NOTE: Transfers into Trade in 1967 = 5,717, 46TM = 163,365
 $\Rightarrow TR/GTM = .035 (= 3\%)$. Since $(\frac{6TM}{GVA})_{1972} = .913$, this indicates small errors

7/30/80

$$1. \text{ Thus if } \left(\frac{GTM}{GVA^*} \right)_{1967} \approx \left(\frac{GTM}{GVA^*} \right)_{1972} = .213$$

Suppose GTM_{1967} = cars listed in I-O

$$GTM \left(1 + \frac{\Delta R}{GTM} \right) = GTM'_{1967} = GTM (1.035)$$

$$\text{Then } \left(\frac{GTM'}{GVA^*} \right)_{1967} = \left(\frac{GTM}{GVA^*} \right)_{1967} (1.035) \approx (.213)(1.035)$$

$$\therefore \left(\frac{\Delta GTM}{GVA^*} \right)_{1967} = (.213)(.035) = \pm .007$$

This is a negligible difference in practice

8/7/85

I VALUE SIDE (INCLUDING ADJUSTMENTS for pre-1972 years treatments of Secondary Products)

$$1. \quad \boxed{GV^* = GV_P^* + GV_{TT}^*}$$

where $GV_P^* =$ Gross Value Realized in Production Sector

$$= \underbrace{(m_P - ADJ_m)}_{m_P^*} + \underbrace{(Y_P + SC_P - ADJ_Y)}_{Y_P^*}$$

$GV_{TT}^* =$ Gross Value Realized in Total Trade (Wholesale/Retail/BR) Sector

$$= \underbrace{\left[m_T + (m_R - m_{IMPR}) - ADJ_Y \right]}_{m_{TT}^*} + \underbrace{\left[(Y_T + SC_T) + (Y_R + SC_R - Y_{IMPR}) + ADJ_Y \right]}_{Y_{TT}^*}$$

$$2. \quad \boxed{GVA^*} \equiv GV^* - m_P^* = \boxed{Y_P^* + (m_{TT}^* + Y_{TT}^*)}$$

Note that we could calculate totals even more easily than the above, since terms like $m_P + SC_P$, $m_T + SC_T$, $m_R + SC_R$ are simply the recorded totals of P, T, R "intermediate inputs". Similarly, ADJ_m and ADJ_Y in GV_P^* could be estimated as the total ADJ_{60} , while ADJ_Y appears as both a negative and positive number in GV_{TT}^* .

8/7/85

The principal reason for not simplifying the calculation process too much is that this way we can see the various ^{base} components of GU^* , GVA^* — which is important for analysis of the overall patterns

II USE SIDE (Including Secondary Product Adjustments)

$$1. \quad \boxed{GU^* = (U_P + U_{TT} + U_F) + C' + I' + G'}$$

where $U_P + U_{TT} + U_F$ = total intermediate use (output used exp as intermediate inputs) in production, total trade and finance

$$= \underbrace{(m_P - ADJ_M)}_{m_P^*} + \underbrace{(m_T - ADJ_Y)}_{m_T^*} + \underbrace{(m_R - \cancel{ADJ_{PR}})}_{m_{BR}} + m_F$$

$$C' = \text{personal consumption of total product} \\ = (C - Y_{EMPR} - SC_H)$$

$$I' = \text{investment and unintended inventory change} \\ = (I - A_{BR})$$

$$G' = \text{government consumption of total product} \\ = (G - Y_G - SC_G)$$

$$(X-M)' = \text{net exports} = (X-M) - SC_{X-M}$$

$$2. \quad \boxed{GFU^* = GU^* - m_P^* = (m_T^* + m_{BR} + m_F) + C' + I' + G' + (X-M)'} \quad \boxed{}$$

where $m_P^* = m_P - ADJ_M$ = true intermediate output in prod. sector (exclusive of finance changes)
 $m_T^* = m_T - ADJ_Y$

8/7/85

III EQUALITY OF TWO SIDES

$$\begin{aligned} \textcircled{1} \quad GVA^* &\equiv Y_P^* + (m_{TT}^* + Y_{TT}^*) \\ &= \underbrace{(Y_P + SC_P - ADJ_Y)}_{Y_P^*} + \underbrace{[(m_T - ADJ_Y) + (m_R - m_{IMPR})]}_{m_{TT}^*} + \underbrace{[(Y_T + SC_T + ADJ_Y) + (Y_R + SC_R - Y_{IMPR} - ABR)]}_{Y_{TT}^*} \\ &= (Y_P + Y_T + Y_R - Y_{IMPR} - ABR) + (SC_P + SC_T + SC_R) + [(m_T - ADJ_Y) + (m_R - m_{IMPR})] \end{aligned}$$

$$\text{But } Y \equiv Y_P + Y_T + Y_R + Y_G + Y_F \Rightarrow Y_P + Y_T + Y_R = Y - Y_G - Y_F$$

$$\therefore \textcircled{1}' \quad GVA^* = (Y - Y_G - Y_F - Y_{IMPR} - ABR - Y_F) + (SC_P + SC_T + SC_R) + [(m_T - ADJ_Y) + (m_R - m_{IMPR})]$$

$$\begin{aligned} \textcircled{2} \quad GFU^* &\equiv (U_{TT} + U_F) + e' + D' + G' + (X - M)' \\ &= [(m_T - ADJ_Y) + (m_R - m_{IMPR}) + m_F] + (C - Y_{IMPR} - SC_H) + (I - ABR) \\ &\quad + (G - Y_G - SC_G) + [(X - M) - SC_{X-M}] \end{aligned}$$

Note that $FD = Y = C + I + G + X - M$.

$$\textcircled{2}' \quad GFU^* = [(C + I + G + X - M) - Y_G - Y_{IMPR} - ABR - (SC_H + SC_G + SC_{X-M})] + m_F + [(m_T - ADJ_Y) + (m_R - m_{IMPR})]$$

Now $GVA^* \stackrel{?}{=} GFU^*$ if the noncommon terms are equal. I.E.

$$\text{if } -Y_F + (SC_P + SC_T + SC_R) = -(SC_H + SC_G + SC_{X-M}) + m_F$$

$$m_F + Y_F \stackrel{?}{=} SC_P + SC_T + SC_R + SC_H + SC_G + SC_{X-M}$$

⇒ But this is simply equality of COL. & ROW SUMS OF FINANCE SECTOR

Note That treatment of
rental sector and finance
sector must be reworked

① All Rents paid by business
are listed as intermediate costs
But ~~all~~ rents received by
Non-rental bus. are added to
TR of R+R sector

② On other hand, ^{only imputed} ~~net~~ interest
paid is listed in IO/NIAA, &
this is in VA, NOT costs.

Cement Transformation of I-O/NIPA Accounts

8/5/84

1. The first step is to distinguish productive sectors from unprod. ones

- (i) Productive Sectors — Agriculture
Mining
Construction
Manuf.
(Productive) Transp and Public Utilities
Productive Services

(This includes productive govt enterprises, since NIPA lists them under ^{appropriate} value categories)

- (ii) Unproductive Sectors — Trade
FIRE
Unprod. Services [Including unprod. govt. enterprises]
[General government]

2. Second step is REMOVAL OF FICTITIOUS ELEMENTS (see "Summary: Imputations in GNP", 8/5/84)

- (i) Sectoral Side a) Fictitious Rental GNP is 60% of total rental GNP, in 1976. ^{adjustment}
Note that for I-O table, the intermediate goods & services component ~~is explicitly~~ of fictitious rents is explicitly listed in NIPA, Table 8.8, line 73). $Z_R \downarrow$ by 60%

check this against I-O conventions

- b) Fictitious Finance GNP is 40% of total financial sector gross product ^{in 1976}. Here, no component of materials cost is affected since the fictitious element is allocated to GNP alone. $Z_F \downarrow$ by 40%

Note that fictitious interest received is part of net interest in V.A.

- (ii) Final Use Side — Remove fictitious elements from $\left\{ \begin{array}{l} C \downarrow (-12\%) \\ I \downarrow (-1\%) \\ G \downarrow (-1\%) \end{array} \right.$

Since the ~~two sides~~ total adjustments to the two sides is the same, the I-O and NIPA double-balance tables will balance after adjustment

Final/Unprod
 - Fixed
 - Double counted
 = Reallocation
 + excluded items (GDP)

8/5/84

3. Third Step is REMOVAL OF DOUBLE COUNTED ITEMS, from Marxian point of view

(1) GOVERNMENT (NON PRODUCTION = GENERAL GOVT)

Because the "general" ^{use of} "govt." is treated as part of final product and also a "producer", we have double counting from our point of view

a) On Sectoral Product Side: $Z_G = Y_G \equiv W_G$ is counted as the "govt. product" (GNP and GNP). This has to be removed
 $\Delta GNP = (\Delta Z)_G = -W_G$

b) On Final Use Side: The cons. of govt. workers is already in Aggregate Cons. (C), but on top of this the wage cost of govt. employees is also included as part of the cost price of the total gross output of the government = $G = M_G + W_G$, where M_G = govt. purchase from business (all treated as current consumption). Thus W_G has to be reduced from final use of actual product, from G column (since C_{W_G} is truly a final use of Dept II's product).

$\Delta GNP = \Delta G = -W_G$

c) On Aggregate Income Side: The ^{private} sources of govt. ~~expenditure~~ = indirect taxes + direct taxes + govt. ~~deficits~~ are already listed here, and the compensation of govt. employees is then further counted under "Employee Compensation". But this is double counting, since the latter is merely a portion of the former recirculated (transferred) to workers via the state. So Employee Compensation must be reduced by $-W_G$

$\Delta GNP = \Delta EC = -W_G$

(11) Ground Rent and Finance

a) GR_B paid by business

b) GR_C paid by consumers

$GR_B =$ we give ground rent paid by bus same treatment as trade sector (so put it under re-allocation)
 FR - I-O treats this differently from rentals

(4) Ground Rent

a) GR_B paid by business = Gross rents paid by business (since rental receipts of business are listed as receipts of rental sector)

a cost, In I-O tables, all rent ($BR_B + GR_B$) paid by ^{non-rental} businesses is listed as an "intermediate input" of the non-rental bus. sector. Of this, one portion is building rent (BR_B), and should be left where it is. The rest is ground-rent GR_B . Similarly, all rent received by non-rental business is listed as a Receipt of the "Rental sector"

① GR_B is most easily treated as leaving + where it is, above the VA line of non-rental business, and then counting the expanded value added of the GR_B sector as part of total ~~national~~ value added ["I-O Accounts", 31]. Note that ground-rent paid by the GR sector to itself must be eliminated, since this is a purely internal transfer ("I-O Accounts", p. 30). Column + Row reduced. This does not affect Y .

$$Y^w = Y_p + Y_T^* + Y_{GRB}^* = (Y_p + Y_T + Y_{GRB}) + (t+m) + (d+u)_{GRB}$$

The treatment ^{of GR_B} is identical to that of TRADE sector

② Alternately, GR_B can be separated out from R_B , and transferred (as net ground-rent paid) to value-added portion of each sector. This expands the value-added of non-rental business by ~~$\sum_{i=1}^N GR_{B_i}$~~ $\sum_{i=1}^N GR_{B_i} = TR_{GR_B}$, so the corresponding column of GR_B sector must be

transferred column ~~with an entry~~ on FD side, to balance tables.

Current Transformations of I-O/MIPA

4. Fourth Step is REALLOCATIONS

- (i) Unproductive activities within productive sectors ~~are~~ must be reallocated to corresponding Trade, ^{GRB}GRF, etc. sectors
- a) Use $(W_U)_p$ as starting point. But use the ~~corrected~~ reallocated Trade, GRF, etc. sectors to estimate the Trade, GRF, etc. components of unproductive ~~sectors~~ and the relations between $(W_U)_p$ and the intermediate costs, deprec, profits, taxes, etc. which should be reallocated from prod. sectors to unprod. ones
- b) This in effect assumes that unprod. activities within productive sectors most closely resemble the corresponding activities in the corresponding unproductive sectors. This point is important because there are great differences in intermediate costs in prod. & unprod sectors, for instance

(ii) Building Rental portion of FIRE must be reallocated to Trade sector

(iii) Ground Rent & Finance paid by Business must be treated as a direct transfer ("tax")
→ reallocation to? Trade (expanded) Transfers (GRF, etc.)

(iv) Unprod. Services must be treated as Reallocated (Eliminated due to double counting) — i. s.

→ This includes treatment of households & non-profit/institution services (HI)

5. Final step is expansion of concept of National Product to include depreciation & materials of Expanded Trade sector [T + BR + (Trade) ^{prod. sectors}]

(i) Amortization of Buildings must be excluded from DBR → $d_{BR} = D_{BR} - A_{BR}$

 - ② Separate into Prod/Trading/Transferring/Other
 - ③ Reallocate unprod. Activities within Prod. Sector to —
 - ④

Notes on the ^{De-}Construction of Input Output Tables

In what follows, it is important to note that the methodology of the 1972 table is quite different in several respects from that of earlier tables. Therefore the starting point will always be the new method. Also, the focus here will be on the implications of I-O conventions for the Marxian treatment of the same transactions.

I. Distinction by Activities

The basic Marxian framework requires us to distinguish the following activities (as opposed to sectors) in the I-O accounts.

1. PRODUCTION ACTIVITIES

- Agriculture
- Mining
- Manufacturing
- (Productive) Transportation
- Public Utilities
- Productive Services

Note that government enterprises would be included in the relevant activity category.

2. NONPRODUCTION ACTIVITIES

TRADING ACTIVITIES

- Wholesale and Retail Trade
- Building and Equipment Rentals

TRANSFER ACTIVITIES

- Ground Rent
- Finance and Insurance
- ~~Insurance~~

OTHER NONPRODUCTION ACTIVITIES

- General Government
- Unproductive Services
- Other Business Services (Advertising, etc.)

3. FICTITIOUS ACTIVITIES

- Fictitious Rentals (Owner Occupied Housing)
- Fictitious Finance (Imputed Interest and Services Charges)
- ~~Fictitious Insurance (Imputed Interest and Service Charges)~~

II. Operations on Actual I-O Tables

The most efficient way to operate on the actual table seems to be:

Remove Fictitious Activities and rebalance tables

Separate Sectors into Production, Trading, Transferring, and Other Nonproduction Sectors

Transform Sectors to Activities by reallocating nonproduction activities within production sectors, and production activities within nonproduction sectors, to the appropriate activities columns. (Much of this is already done in the I-O tables themselves, except for certain nonproduction activities in the production sectors).

Calculate the relevant Marxian measures from these transformed I-O tables.

With this procedure in mind, we will now detail each step.

1. REMOVING THE FICTITIOUS ACTIVITIES.

A. Fictitious Rentals

In NIPA/I-O methodology,

Classified Sec Albert J. Waldenbury
The Composition of Value Added in ~~FOF~~
The 1963 I-O Study", SCB, April 1972

JULIE — Are there NIPA tables
consistent with I-O, as
promised in SCB —
Michel

Note on GR

GR paid by $P+T+BR$ → TR_{GR}^{sector}

∴ Explicitly treating $GR_{P,T,BR}$
will not change GV^* , since
it will ~~remove~~ TR_{GR} from TR_R
and add the same amount to
 $GV_{P,T,BR}^*$.

But it will change GVA^* , S^*
because it is an addition to $GVA_{P,T,BR}^*$
and not to (mp) ✓

Financial Flows & Measure of S.V.

5/1/85

1. One remaining question has to do with the treatment of net interest out of wages (& cap. income, etc.) rather than directly out of profits of productive sector

(1) Suppose $GVA^* = 1600 = 600_{W_p} + 1000_S$

(ii) If \$100^{=NIP_p} were paid out of S to finance sector, then re-circulation of this value causes nominal ~~GVA~~^{TR, GVA} to rise, because the NIP_p = \$100 is counted as part of GVA of productive sector, and is then again counted as part total revenue of Finance sector. But this is merely double-counting. If we count once only, then we can count either, but not both.

$$GVA^* = 600_{W_p} + 1000_S = 600_{W_p} + [900_{\pi_p} + 100_{NIP_p}]$$

$$= 600_{W_p} + [900_{\pi_p} + \underbrace{100_{TR_F}}_{\substack{40_{m_F} + 30_{w_F} + 30_{\pi_F}}}]$$

$$\therefore 1000_S = 930_{\pi_F} + (40_{m_F} + 30_{w_F})$$

$$\Rightarrow \boxed{GVA^*} = \boxed{GVA_p} + \cancel{NIP_p} + W_p + \pi_p + NIP_p$$

$$\boxed{GVA^*} = (GVA_p - NIP_p) + (W_p + \pi_p + NIP_p)$$

$$= (W_p + \pi_p) + (m_F + w_F + \pi_F)$$

$$\boxed{S = (\pi_p + NIP_p) = (\pi_p) + (m_F + w_F + \pi_F) = \pi + m_F + w_F}$$

(iii) Now suppose that, instead, \$100 is paid out of prod. worker wages as $(NIP)_{w_F}$

In this case also, the original \$100 is

4/17/85

Summary: Prod, Trade, & Rental

If we require consumer ground-rent, we can say that $Y_{GR} + m_{GR} \approx 0$; also, if we compensate for this by treating $ABR \approx Deprec_{BR}$, then

$$GVA^* \approx Y_P + (Y_T + m_T) + (Y_R + m_R) - DR - Y_{RF}$$

$$GVA^* \approx [Y_P + Y_T + (Y_R - Y_{RF} - DR)] + m_T + m_R$$

This leaves in Y_{GR} but takes out $(DR - ABR)$

$$GFU^* \approx C + I + m_T + m_R - DR - Y_{RF}$$

$$= [(C - Y_{RF}) + (I - DR)] + m_T + m_R$$

Summary: P + I + Govt } take out of every element, in a total amount $Nt = DR = \sum I_R$ } But for now, just take out rental row for convenience

take out ~~rent~~ rental row, because that's where there add this ~~particular~~ function

GOVERNMENT

$$GVA^* = Y_P + (Y_T + m_T) + ~~m_G~~ = Y - Y_G + m_T$$

$$GFU^* = (C - Y_G) + I + G + m_T = (C + I + G) - Y_G + m_T$$

$$= E_{private} + I + G + m_T = PD - Y_G + m_T$$

$$GVA^* = \underbrace{\{ (C + I)_{private} + m_T \}}_{Y + m_T} + G$$

Rental Sector

3/4

4/17/8

BR

Trade activity. Once you ~~recognize~~ ^{purchase} put buildings to be rented are DNV , must subtract ABR from I_{BR} and also subtract ABR from Y_{BR} (where it is hidden in $Depr. BR$). Other than that, BR is same as trade...

→ Bus. expenditures on BR are part of ^{their} intermediate, & consumer ^{expenditures} on BR are part of ^{their} Y_{BR}

	Prod	Trade	BR	$C + I + G$
Prod				
Total Wholesale/Retail				
Trade Rental			$-ABR$	$-ABR$
GVA	GVA_P	GVA_T	GVA_{BR}	

→ Y_{BR} ~~Y_{BR}~~ ^{$+m_{BR}$} shows up explicitly as part of value added, ~~and~~ ^{since} m_{BR} is added to it represents GTM of BR. But $-ABR$ must be taken out.

→ On FU side, $W_{BR} + \pi_{BR}$ ^{already} show up in $C + I + G$, so we need only add $+m_{BR}$ and subtract $-ABR$ from the rent row of total invest. column

rents paid
Note that BR appears as part of $m_P, m_T, +m_{BR}$, and as part of C, I, G (just as trade margins do)

C. d
 Owners Occupied houses, Sector $\left\langle \begin{matrix} (m_{BR}) \text{ Fict} = \text{real home maintenance} \\ (Y_{BR}) \text{ Fict} = \text{completely fictitious} \end{matrix} \right.$

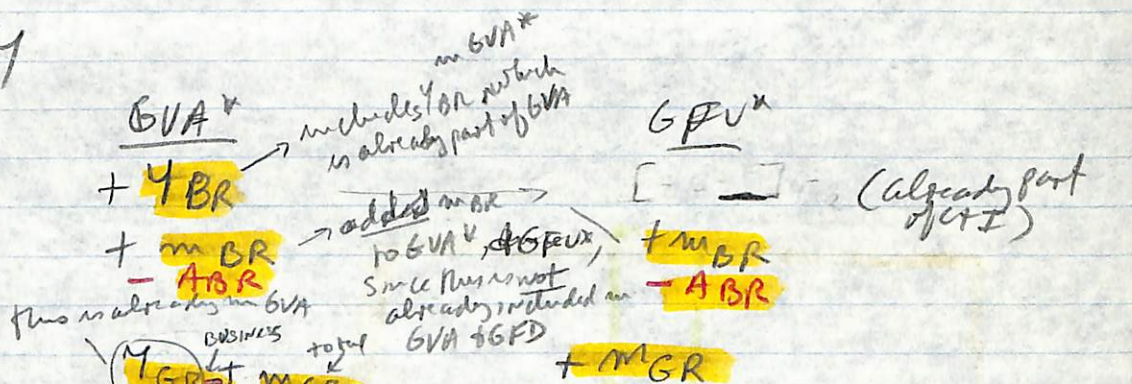

rental

Take this out of Y_{BR}

Rental Sector

1/2

4/17/85

- ① Not all P+R is rental (~10% = sales)
 For Rentals, two parts \leftarrow Ground Rent \leftrightarrow Transfer like Finance & Tax
 Building Rent \leftrightarrow Secret here is that this sector is really a trading sector
- ② Building Rentals
 Do all BR first

A. Ground-Rent

This is formally identical to interest & finance charges, as far as Marxian accounts go.

In MPA accounts, it is listed directly as part of ~~prod~~ GRs row of prod + trade sectors ("purchases of land services" from GRs) and this same sum shows up as TR of GRs sector, split into $m_{GRs} + VA_{GRs}$. This is exactly ~~the same as~~ the deferral treatment of ^{business} finance sector is payment, ~~is~~ ~~but~~ though the ~~former~~ finance treatment is covered at by first listing net int paid in VA of P+T, then creating fictitious "imputed" interest & service flows, it thus effectively transfers net int. paid by P+T into an "intermediate input".

For this reason, the Marxian ~~and~~ MPA/I-O relation in the case of ground-rent paid by business is the same as for ^{finance charges &} net int. paid. ~~Table~~ Figure 14

below summarizes this

Figure 14: Marxian + I-O Accts for Business Ground Rent

	Prod	Trade	Bus Ground Rent	FINAL DEMAND	
				C	I
Prod	xx	xx	xx	xx	xx
Trade	xx	xx	xx	xx	xx
BUS GR. Rent	xx	xx	xx	25 GFV _{tr}	
Wage	xx	xx	xx	GVA _{tr}	
Profit	xx	xx	xx		
GVA	xx	xx	xx		

Note: In the original image, the 'Bus Ground Rent' row is highlighted in yellow. A red box encloses the 'Trade' and 'Bus Ground Rent' rows. A red arrow points from the 'Bus Ground Rent' row to the 'GVA_{tr}' label. The 'Bus Ground Rent' cell contains 'xx' with a circled 'x' and the text 'Not included' next to it.

$$GVA^b = Y_p + Y_r + m_r + GR_p + GR_r$$

$$GFV^b = C + I + m_r + m_{GR} + GR_B$$

Consumer GR — Same treatment. In effect, ~~like~~ ^{unlike} case of ~~Business~~ ^{Business} ~~GR charges~~, these are also already counted in GVA — but here, disguised as part of wages & profit revenue. So they are just ~~not~~ ^{part} of them are paid by ~~not~~ ^{paid} rental bus. to rental, only through ~~mediation~~ ^{mediation} of consumers \Rightarrow included to include ~~not~~ ^{not} GR_H

B. Building rentals

Buildings counted as K-stock of B+R sector (hence amortization \rightarrow BIAS in using stock?)

The ~~business~~ ^{activity} of renting buildings ~~to~~ is a business ^{activity}, which buys commodities (buildings) and then sells them again, in piecemeal form. ~~The piecemeal sale of a building is accomplished through the annual rental of renting it out over its lifetime to a series of users.~~ ^{the process} The annual building rental payments are therefore the annual piecemeal purchases of the building, which over its lifetime exhaust its use.

Trader buys 100 of stock, adds it to IAW $\rightarrow \Delta I = \Delta IAW = 100$
 sells 50 of it, for 60 $\rightarrow \Delta I = \Delta IAW = 100$
 suppose 10% of stock detaches?

From the above point of view, the building rental sector is really a trading activity. Lit

Note that there is an asymmetry in the NIPA/I-O treatment of gross invest versus ΔINV :

womenly, gross invest. includes replacement invest \Rightarrow gross change in the K-stock, whereas ~~whereas~~ ΔINV is a net change in stock of inventories. ^{IE. they treat inventory invest as net of fixed capital invest as gross (since VA has depreciation)}

Thus when we move ~~to~~ ^{to} purchases of buildings-to-be-rented from (IG) column of BR to ~~to~~ ^{to} ΔINV column of this sector, we have to switch from gross additions to net additions in order to be consistent \Rightarrow hence subtract Amortization of buildings to-be-rented.

Verify this by analogy

Building Rental

4/17/85

(1) BR \leftrightarrow Trading Sector

A. Trade Sector
(1)

Suppose Trade sector buys \$100 in stock,

$$\rightarrow (\text{Invest})_T = \Delta \text{INV}_T = +\$100$$

(ii) when it sells this for \$120, it deducts \$100 from INV_T (at cost)

$$\Delta \text{INV}_T = -100$$

and adds it to intermediate input: $m_T = 100$

$$\rightarrow \text{GDP}_T = m_T + \text{GTM} = 100 + 20 = 120$$

(iii) The buying business adds it amount to its stock of inputs at \$120, and when it uses this it reduces INV_B by 120 + increases m_B by \$120 (so net change in invent = 0)

B. Building Rental

(i) BR sector buys \$1000 in buildings to be rented out (or resold) $\rightarrow \Delta \text{INV}_{BR} = +1000$

- (ii) Over its lifetime, it rents this out for $\$1,200 = 1000 + 200$
cost VA
- Deducts cost from stock $\Rightarrow \Delta INV_{BR} = -1000 = -A_{BR}$
- Adds $\$1000$ to int. input $\Rightarrow m_{BR} = 1000$
- Adds $(GTM)_{BR} = 200$ to this to get gross output $= 1200$

- (iii) The ^{business} renter of this building treats it as a pure flow cost ^{of \$1000} (adds to $INV = +1200$ & "subtracts" to $INV = -1200$, so net change in $INV = 0$) as part of m_{BUS} of the same year

It should be clear from the above that ~~the~~ building rental is ^{on this context} merely a trade activity "stretched out" over a longer interval

- Treat $BR_B + BR_C$ as a trade sector
- ~~NEED~~ **NEED** TO ADJUST FOR A_{BR} ^{should be} (in trade)
comes from FACT that ~~A~~ is not listed as

3
4/17/05

② The formal similarity of Building Rental & Office trading sectors can be illustrated as follows: Prod sector produces a product of \$2000, which it then sells to trade and \$2000 to BR sector. These ~~latter sectors~~ ^{are then} added to inventories in the latter sector. To the extent that ~~trade~~ ^{either} sector sells the ~~product~~ ^{counted} goods purchase (sold outright by trade, sold piecemeal by BR), it deducts the cost from inventories & lists it as ~~intermediate~~ costs. But to the extent a portion of these goods are not sold, they appear as investment, either intended or unintended (SPNV). Here they are recorded at purchase's prices, even ~~though they are~~ ^{since they are} treated as having been (voluntarily or involuntarily) "purchased" by the trading of BR sectors themselves for investment. ~~prices.~~

Fin. Flows & SV

5/1/85

already counted as part of $GVA^* = GVA_P$, since it is already counted in wages w_p . So we ~~measure~~ measure ~~so~~ GVA^* in ~~the~~ ~~same~~ way as before

$$GVA^* = (GVA_P) = W_p + \pi_p$$

But since wages w_p now consist of net wages w_p' and net int. paid out of wages NIP_{w_p}

$$\therefore GVA^* = W_p + \pi_p = w_p' + (\pi_p + NIP_{w_p}) = 1600$$

But NIP_{w_p} shows up as $TR_F = m_F + w_F + \pi_F$

$$\therefore \boxed{GVA^*} = w_p' + (\pi_p + m_F + w_F + \pi_F) = 1600 \\ = \cancel{W_p} + \pi_p = \boxed{GVA_P}$$

So here too, either we count GVA_P only, or we have a reduced $GVA_P' = w_p' + \pi_p$ supplemented by $TR_F = GVA_F + m_F$

But the real ^{question} difference arises for measure of surplus value. If we define S as $GVA^* - W_p$, then $\underline{S} = GVA^* - W_p = \pi_p < \pi_p + (\pi_F) = \pi$

This implicitly treats ^{aggregate} surplus value as difference between gross value added and nominal wage w_p , so that ~~revenue~~ unlike previous instance, revenue of finance does not get counted at all in surplus value (though it does in GVA^*)

Alternately, we could define $S' = GVA^* - w_p' = GVA^* - (W_p - NIP_{w_p}) \\ \Rightarrow S' = \pi_p + (m_F + w_F + \pi_F) > \pi$

5/1/85

2. It seems that on the above basis we should count surplus value as GVA^* minus net production worker wages (net of ^{net} interest, finance charges, ~~and~~ ground rent, and net tax paid).

This would make our procedure consistent throughout, and brings the measure of surplus value into conformity with ^{the total of} aggregate profits and circulation costs.

Note that ~~totals~~ S does not have to be adjusted for trade & rental sector finance flows — only changes in W_p affect S .

(i) Insofar as interest paid by trade sector itself is concerned, it raises no new problems, since NIP_T is already counted as part of GVA^* (under GVA_T). So we cannot count Finance sector on VA side at all, unless we reduce GVA_T by NIP_T .

either: $GVA^* = GVA_p + GVA_T + m_T \Rightarrow S = GVA^* - W_p$
 $\Rightarrow S = \pi_p + TR_T + TR_F$

or $GVA^* = GVA_p' + GVA_T' + m_T + (m_F + W_F + \pi_F)$

where $GVA_p' + GVA_T' = GVA_p + GVA_T - (NIP_p + NIP_T)$

and $NIP_p + NIP_T = TR_F = m_F + W_F + \pi_F$

(ii) As for int. paid by trade sector workers, it is also already counted as part of GVA^* (under W_T), so cannot be counted finance sector on VA side unless we reduce W_T by NIP_T . In either case, however, the total $GVA^* + S$ are unchanged: $GVA^* = GVA_p + GVA_T + m_T - GVA_p - GVA_T - NIP_T + (TR_F)$

chart.

$$\left\{ \begin{array}{l} GVA^* = GVA^*_P + GVA^*_T + \dots \\ GFU^* = C^* + I^* + \dots \end{array} \right.$$

3. Check to see if reallocation of secondary products in I-O sectors means that $(W_P)_{I-O} \cong (W_P)_P$ in NIPA
 \Rightarrow Should reduce but not eliminate ~~diff~~ $(W_P)_I$

Sube

- (1) Table: Break I-O GVA into broad components: Y_P, Y_T, Y_F, Y_R, Y_G
— Compare these to NIPA

7/30/85

1972 & Earlier Tables: Differences

I Secondary Products

1. 1972 redefines all secondary products

(i) Output of secondary product is reallocated to industry which ~~is~~ primarily produces such products

(ii) ~~Input~~ A relevant mixture of inputs is also reallocated

(1972 Def. & Convention, p. 49)
I-0

2. Earlier tables used mixture of redefinition and transfers.

~~(i)~~ Transfers:

(i) Secondary product was treated as if it was sold to primary producer, and then added to the output of that (primary) industry.

1972 of Earlier Tables: Differences 7/30/8

(11) To Trace this, let us first imagine that there are two ~~industries~~ ^{products} (Steel & iron) which appear as two establishments
 $A = \text{Steel} + \frac{1}{2} \text{ iron}$
 $B = \frac{1}{2} \text{ iron}$

By Commodity

	Steel	Iron	C	I	GO
Steel	50	100	350	500	1000 ✓
Iron	100	300	300	300	1000 ✓
W	250	300			
T	600	300			
GO	1000	1000			

To combine these by establishments table must be reallocated and rebalanced

- $\frac{1}{2}$ of iron column must be combined with steel to get Establishment A input structure
- Then, $\frac{1}{2}$ of steel sales must be added Est. A row to get Establishment A sales

7/30/80

By Establishment A = Steel + 1/2 Iron
 B = 1/2 Iron

	<u>A</u>	<u>B</u>	<u>C</u>	<u>I</u>	<u>GO</u>	<u>TR</u>
A	225	125	500	650	1500	✓
B	125	75	150	150	500	✓
W	400	150				
π	750	150				
GO	1500 ✓	500 ✓				
TR	5	5				

(iii) Pre-1972 I-O tables would reallocate by method of transfers

a) Iron in Establishment A is treated as if sold to Establishment B

It therefore is still counted as Establishment A output

Aggregation

(A+I) = (100 + 550 - 500) + 250 + 750
 = 550 = 225 + 125 + 125 + 75 ✓ 650 800 2000

$A_A + A_B + B_A + B_B - TR_B$

W	550
π	900

2000 /
 = GO - TR

Iron purchased by B is also added to B's output (p. 47)

7/30/85

Iron in EST A = \$500 by construction

- Add \$500 to A's sales to B
- Add \$500 to B's output \Rightarrow allocate it along B's row
- Rebalance table, since now it looks like this:

	<u>A</u>	<u>B</u>	<u>C</u>	<u>I</u>	<u>GO</u>
A	225	<u>625</u> (125+500)	500	650	<u>2000</u> (1500+500)
B	125	75	150	150	500
W	400	150			
T	750	150			
<u>GO</u>	1500	<u>1000</u> (500+500)			

Re Balance by moving \$500 worth of iron

distribution (your row) from A to B. List amounts transferred in transfer row & column for use in aggregate

	<u>A</u>	<u>B</u>	<u>C</u>	<u>I</u>	<u>GO</u>	<u>TR</u>
A	100 (225-125)	550 (625-75)	350	500	<u>1500</u> (2000-500)	<u>500</u>
B	250 (125+125)	150 (75+75)	300	300	<u>1000</u> (500+500)	-
W	400	150				
T	750	150				
<u>GO</u>	1500	1000				
<u>TR</u>		1500				

2. (iv) End Result is a table which has
 ... Man here (commodity table)

Commodity Table

	<u>Steel</u>	<u>Iron</u>	<u>C</u>	<u>I</u>	<u>GO</u>
Steel	50	100	350	500	<u>1000</u>
Iron	100	300	300	300	<u>1000</u>
W	250	300			
T	600	300			
GO	<u>1000</u>	<u>1000</u>			

Pre-1972 I-O Table

	<u>Steel</u>	<u>Iron</u>	<u>C</u>	<u>I</u>	<u>GO</u>	<u>TR</u>
Steel	100 ^x	550	350	500	<u>1500</u>	500 = TR ₁
Iron	250 ^x	150	300	300	<u>1000</u>	-
W	400	150				
T	750	150				
GO	<u>1500</u>	<u>1000</u>				
TR	-	500 = TR ₂				

Decreases of GO	<u>Steel</u>	<u>Iron</u>	<u>Total</u>	→ Total inputs are inflated but total VA.F.D is not changed
" " GVA	+500	-	+500	
" " GFD	+300	-300	-	
	-	-	-	

7/30/85

Aggregation of these sectors cancels out this distortion, since ~~the~~ transfer column & rows are used to adjust aggregates

EG, if we aggregate Pre-1972 IO Table,

<u>Prod</u>		<u>C</u>	<u>I</u>	<u>G</u>
Prod	550 ✓ = 100 + 550 - TR ₁ + 250 + 150	650	800	2000 ✓
Wp	550	-	-	
TR ₁	900	-	-	
G0	2000 ✓			

7/30/85

3. Now consider an example of P + T

(i) True Table

	<u>Prod</u>	<u>Trade</u>	<u>C</u>	<u>I</u>	<u>Go</u>
<u>Prod</u>	50	100	350	500	1000
<u>Trade</u>	100	200	300	300	1000
<u>W</u>	450	300	↓ GFD* = 1850		
<u>TI</u>	600	300			
<u>Go</u>	1000	1000	↓ GVA* = 1850		

(ii) Establishment table: $A = \text{Prod} + \frac{1}{2} \text{Trade}$
 $B = \frac{1}{2} \text{Trade}$

	<u>A</u>	<u>B</u>	<u>C</u>	<u>I</u>	<u>Go</u>
<u>A</u>	225	125	500	650	1500
<u>B</u>	125	75	150	150	500
<u>W</u>	400	150	↓ 1650 < GFD* = 1850		
<u>TI</u>	750	150			
<u>Go</u>	1500	500	↓ 1650 < GVA* = 1850		

Note that GVA & GFD are same as in true table
 But now $GVA^* \neq$ values in solid ~~border~~ ~~lines~~

8
7/30/85

(iii) Now Pre-1972 style I=O with transfers (same as in 2 iii?)

	<u>Prod</u>	<u>Trade</u>	<u>C</u>	<u>I</u>	<u>GO</u>	<u>TR</u>
<u>Prod</u>	100	550	350	500	1500	500 TR
<u>Trade</u>	250	150	300	300	1000	
<u>W</u>	400	150	2150 > GFD* = 1850			
<u>TI</u>	750	150				
<u>GO</u>	1500	1000	2150 > GVA* = 1850			
<u>TR</u>	-	500 (TR ₂)				

Now, once again $GVA = GFD = 1450$

but ~~shaded~~ outlined areas do not
add up to GVA*, GFD*

Moreover, the difference is not simply
due to "Transfers" Col/Row, since these
adjustments ~~themselves~~ ~~only~~ were adjustments to
the recorded data in Establishment form
and this form itself is the thing which
needs to be adjusted. [3/11]

7/30/85

Upside of this is that the only
proper way to deal with pre-1972
tables is to recalculate them
in 1972-for. — which means
that

4. Summary

(1) ~~As~~ far as production sectors
are concerned, proper aggregation
(i.e. taking out transfers, as in p. 6)
will cancel out transfers and also
eliminate errors in establishment form
versus (true) commodity form

(11) As far as production sectors
versus trade sectors, the problem
is one of going back &
redefining, rather than transferring,
the trade "service" within production
~~sect~~ establishments.

Note that
in any case,
GVA = GPD = Y
is not affected

BUT NOTE

Transfers into Trade in 1967 = 5,717, 46TM = 63,365
⇒ $TR/GTM = .035 (= 3\%)$. Since $\left(\frac{6TM}{GVA^*}\right)_{1972} = .213$ this indicates
small errors

7/30/85

$$\therefore \text{Thus if } \left(\frac{GTM}{GVA^*} \right)_{1967} \approx \left(\frac{GTM}{GVA^*} \right)_{1972} = .213$$

Suppose GTM_{1967} = as listed in I-O

$$GTM \left(1 + \frac{\Delta R}{GTM} \right) = GTM'_{1967} = GTM (1.035)$$

$$\text{Then } \left(\frac{GTM'}{GVA^*} \right)_{1967} = \left(\frac{GTM}{GVA^*} \right)_{1967} (1.035) \approx (.213)(1.035)$$

$$\therefore \left(\frac{\Delta GTM}{GVA^*} \right)_{1967} = (.213)(1.035) = \pm .007$$

This is a negligible difference in practice
